User guide

Everything you need to assess an AI use case with this kit. The first one takes about ten minutes. There is nothing to install, download or upload.

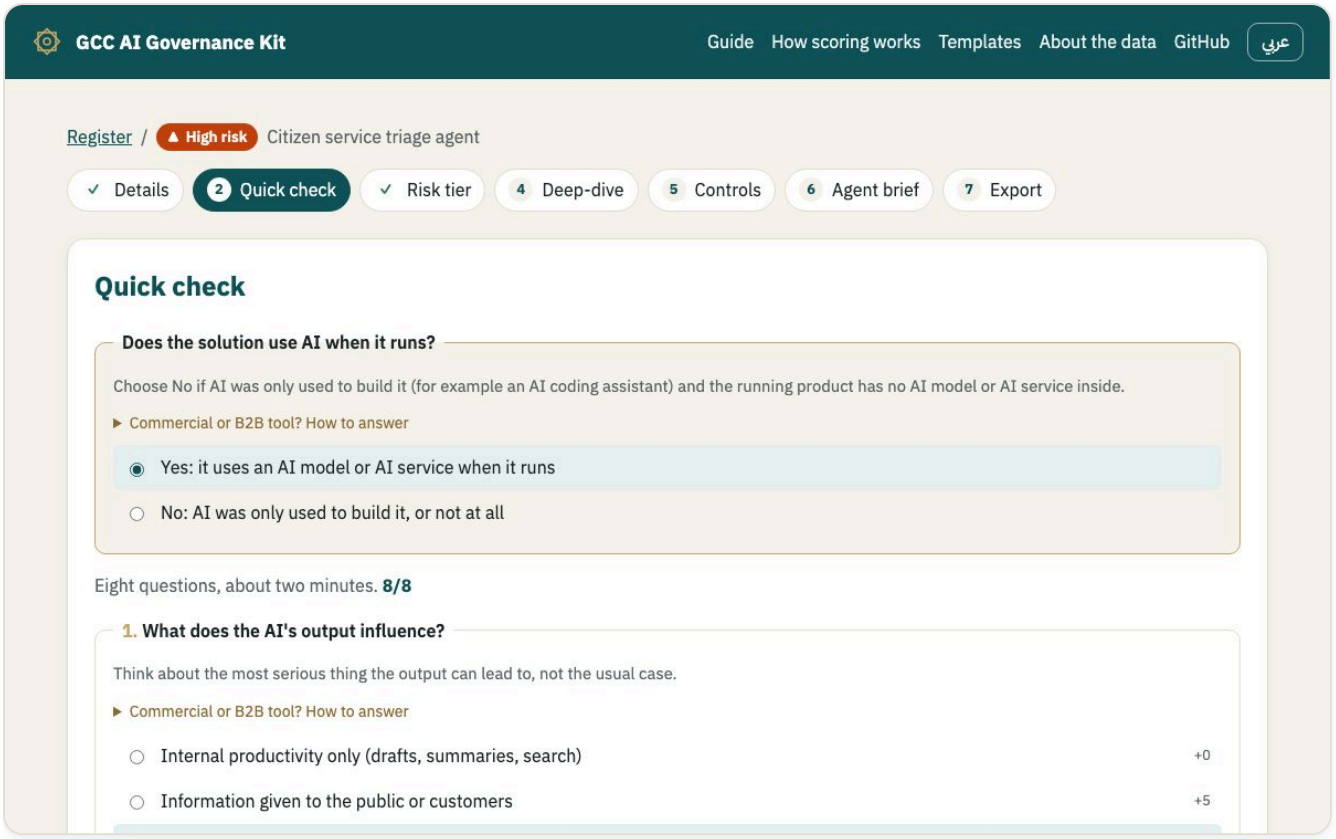

1. Assess a use case in three steps

1. **Add a use case.** On the home page, choose *Start your first assessment*. Give the use case a name and an accountable owner; the other details are optional.
2. **Answer the quick check.** It opens by asking whether the solution uses AI when it runs; if it doesn't (for example, it was only built with AI coding tools), AI governance controls don't apply and the kit gives general software pointers instead. Then come eight multiple-choice questions about impact, data, who is affected, the type of AI, autonomy, oversight, access and reversibility. Each answer shows the points it adds, and these eight questions alone set the tier.
3. **Read the result.** You get a risk tier with the reasons behind it, then the controls that apply under the frameworks you selected, then the exports.

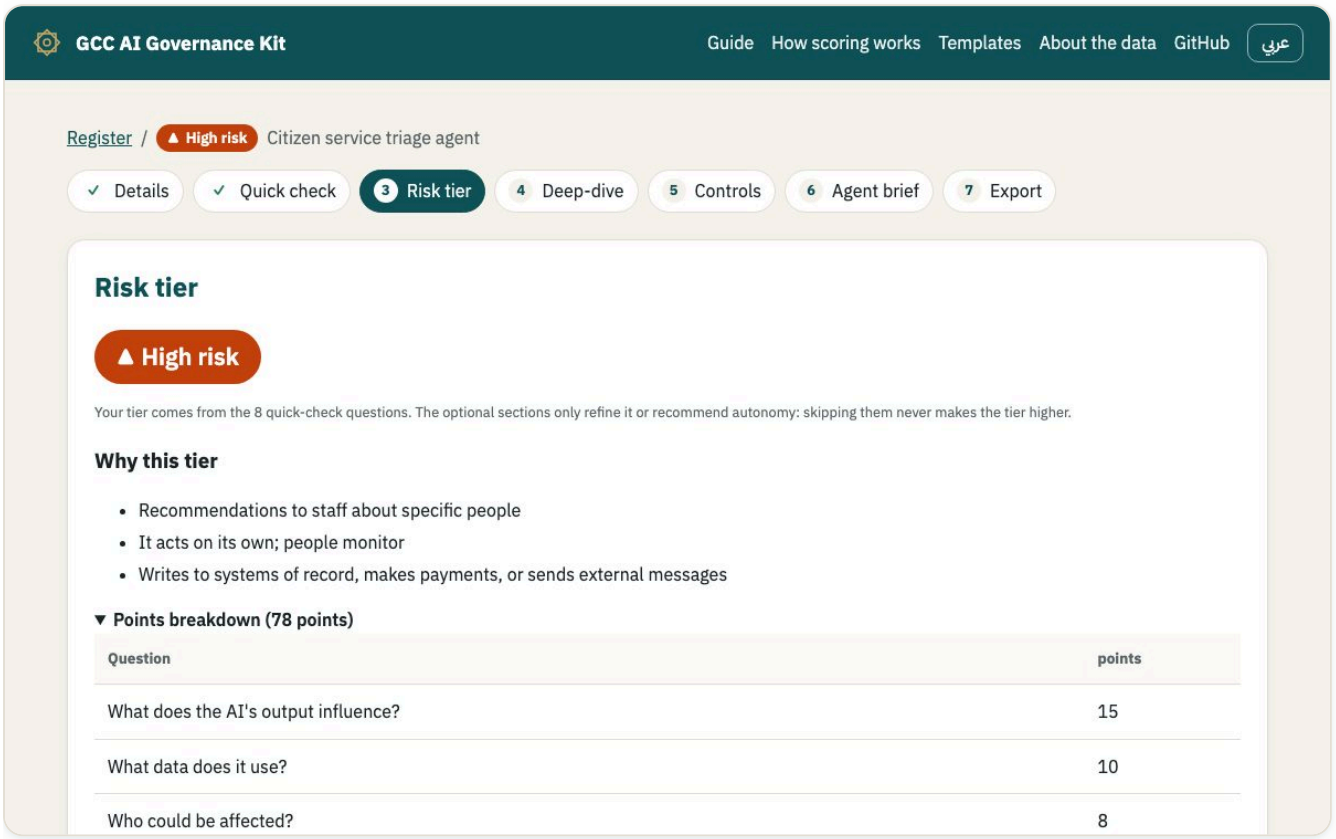

The home page: three steps and one button to start.

Choose the frameworks you follow on the home page. The control list and the exports only show references to those frameworks.

The quick check: eight questions, about two minutes.

For a fuller picture, complete the deep-dive: ten more questions plus three optional prioritisation questions. The deep-dive can raise the tier but never lower it. Complete it before any High-risk use case goes to committee.

The result: a tier, the top reasons and the full points breakdown.

2. What the risk tiers mean

The tier is the higher of two results: the points from your answers, and any named rule that sets a minimum tier. How scoring works lists every weight.

What would lower your tier. Once the deep-dive is done, the tier card shows the tier you would reach by closing operational gaps (testing, monitoring, incident handling, hosting and disclosure), with the points each fix saves. If the tier would not move, the cause is structural (what the AI does, its data, autonomy and access), and only a design change would lower it.

● Little or no risk

Under 20 points. Keep it on the register and apply the baseline controls the kit lists.

◆ Limited risk

20 to 44 points. More controls apply; review them with the accountable owner before launch.

▲ High risk

45 points or more, or a named rule applies (for example, the AI makes decisions about people without a person approving each one). The full control set applies. Complete the deep-dive and take the committee report to your risk committee before launch.

■ Unacceptable

Only through a rule, for prohibited uses such as social scoring. Do not proceed; escalate to your risk committee and legal team.

3. Reading the controls

Controls are grouped by theme: accountability, transparency, data, human oversight, safety and security, and monitoring. Each one says what to do in plain words.

The grey chips are references: the clause, article or principle in each selected framework that asks for the control. ISO/IEC 42001 is cited by clause number only. The numbered links under a control are the official sources used to check it.

Every control carries a verification badge:

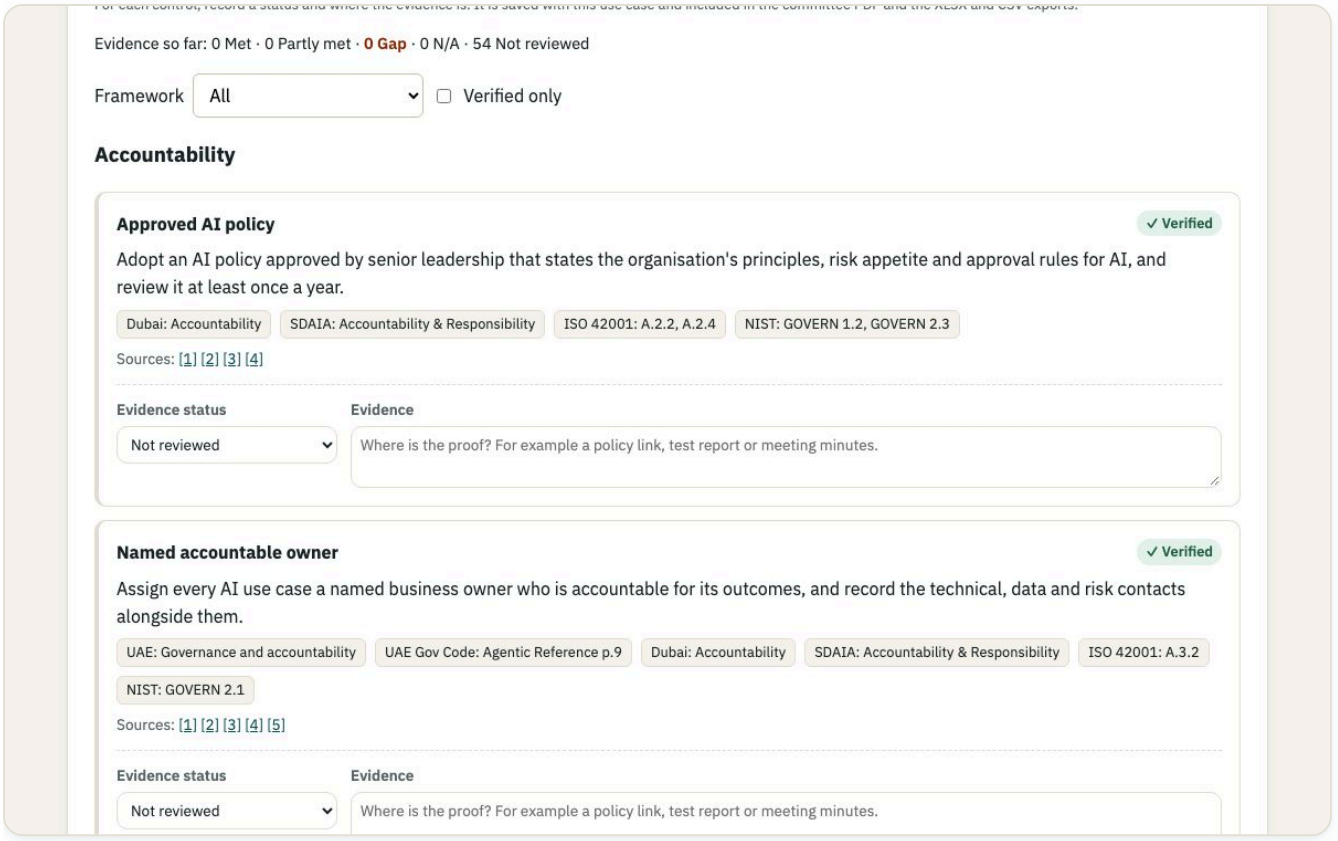

✓ Verified its references were checked against the cited official sources.

Needs verification the control is sound, but at least one reference has not been checked yet. Hover over the badge to see why, and confirm the reference before you rely on it.

Use the filters to show one framework, or verified controls only.

Under each control, record its status (Met, Partly met, Gap or N/A) and where the evidence is, such as a policy link, a test report or meeting minutes. The tally at the top shows your gaps at a glance. The evidence is saved

with the use case, included in your backup, and printed in the committee report and the XLSX and CSV exports.

Controls grouped by theme, with references and verification badges.

4. Recommended autonomy

The three prioritisation questions at the end of the deep-dive (usage, complexity and readiness) recommend how much autonomy the AI should have, from level 1 (full autonomous execution) to level 4 (not suitable for AI yet). The levels are numbered as in the UAE government's AI-assistant priority matrix, so a lower number means more autonomy. They do not change the risk tier.

- **Level 1:** Full autonomous execution
- **Level 2:** Supervised autonomy
- **Level 3:** AI assistance, a person decides
- **Level 4:** Not suitable for AI yet (Not ready for autonomy yet. This is about readiness, not whether AI can help.)

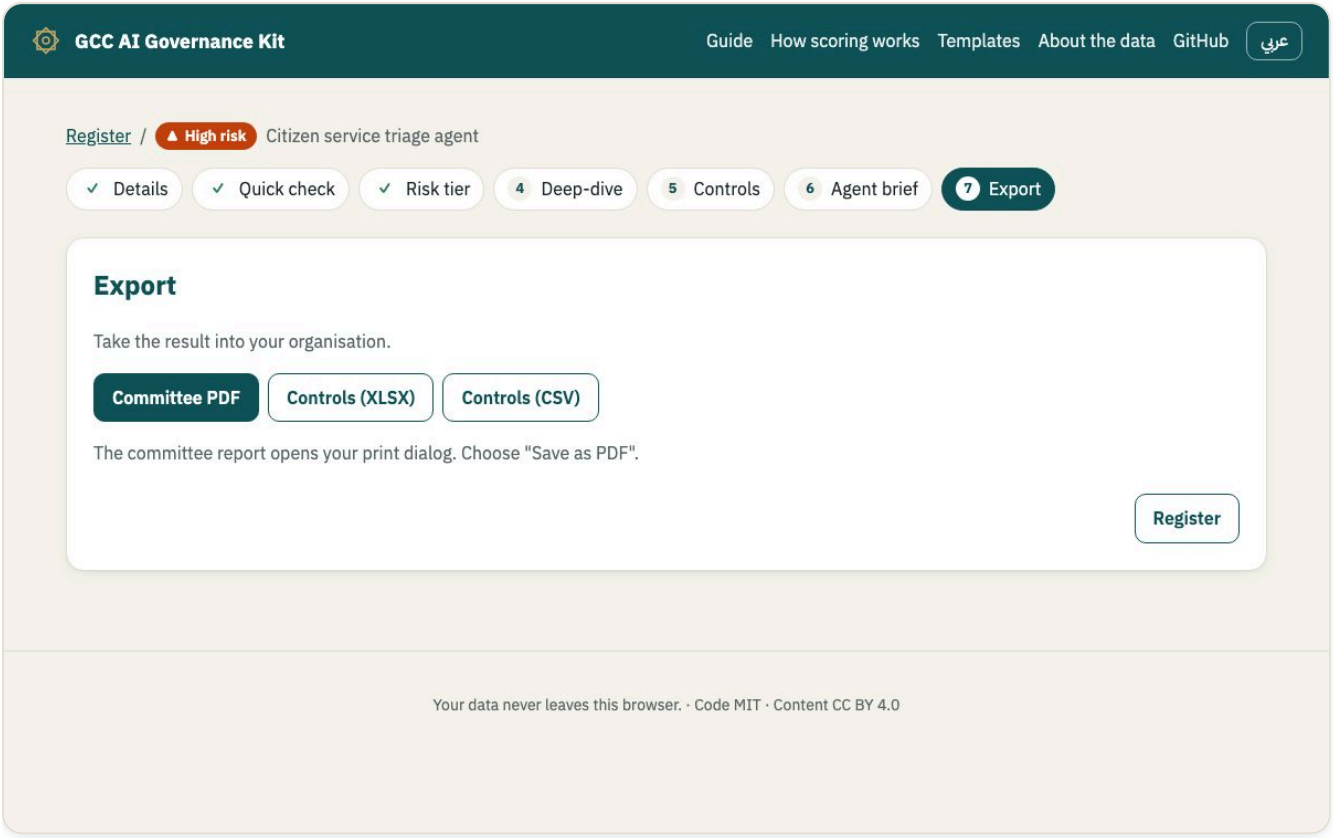

A High tier or a regulated domain never allows level 1: the recommendation stops at level 2, supervised autonomy. If the AI as designed acts more autonomously than recommended, the kit shows a warning: reduce its autonomy or improve readiness first. At level 4 the card lists concrete steps to take first, such as simplifying the process, improving data and naming an owner.

What the AI may do. Under the recommendation, the action matrix sets each of six actions to Allowed, Needs approval or Blocked, pre-filled from the level and the tier. Make a row stricter if you need to; a looser setting is refused, because raising it needs a new assessment. Add limits and the approver's role where they apply.

Release stage. On the Details step, record where each deployment is on the release ladder, from Pre-pilot to Controlled expansion. If it is at Bounded autonomy or beyond while a stop-switch, logging or oversight control is marked Gap, every step shows a warning.

5. Export, share and back up

- **Agent brief.** The step before Export builds a delegation brief from your answers: what the AI is for and when it must stop, what it may do, what must be recorded and when a person steps in. Choose the committee annex or the engineering handover spec, then copy it or download it as Markdown. The brief records what was agreed; it does not enforce it.
- **Committee report.** On the Export step, choose *Committee PDF*. Your print dialog opens; choose *Save as PDF*. The one-to-two-page summary has the tier, the reasons, the control checklist and a sign-off block.
- **Control lists.** Download the controls as XLSX or CSV to track them in a spreadsheet. Arabic sheets open right to left.

The Export step: the committee PDF, and the controls as XLSX or CSV.

- **Back up your register.** On the home page, open *Save or restore* and choose *Save a backup (.json)*. Do this regularly: clearing your browser data deletes the register.
- **Share or move it.** Send the .json file to a colleague. They open the kit, choose *Save or restore*, then *Restore a saved register (.json)*, and can replace or merge their own. For a read-only overview, use *Export register (XLSX)*.
- **Prefer spreadsheets?** The Templates page has the register, impact assessment and control checklist to fill in offline, plus a vendor AI risk assessment, an AI committee charter, a RACI matrix and a one-page release

contract. You don't need them to use the kit. A filled register template can be brought into the app with *Import a filled register* in the Save or restore menu: the tiers are worked out again from the answers.

6. Privacy

The kit has no server. Your use cases are stored only in this browser and are never sent anywhere; you can confirm this in your browser's network tools. Other people cannot see them, and neither can other browsers on your computer. In a private window, or where storage is blocked, the kit warns you that changes will be lost when you close the page, so save a backup.

To remove everything, choose *Clear all data* under the register.

Guidance only, not legal advice. Check obligations with your legal and compliance teams.
